

# Neon Abundance in the Lunar Exosphere from LACE Data

Rosemary Killen (695)

Jaekyun Park (Kyung Hee University, Republic of Korea)

David Williams (690.1); O J Tucker (695)

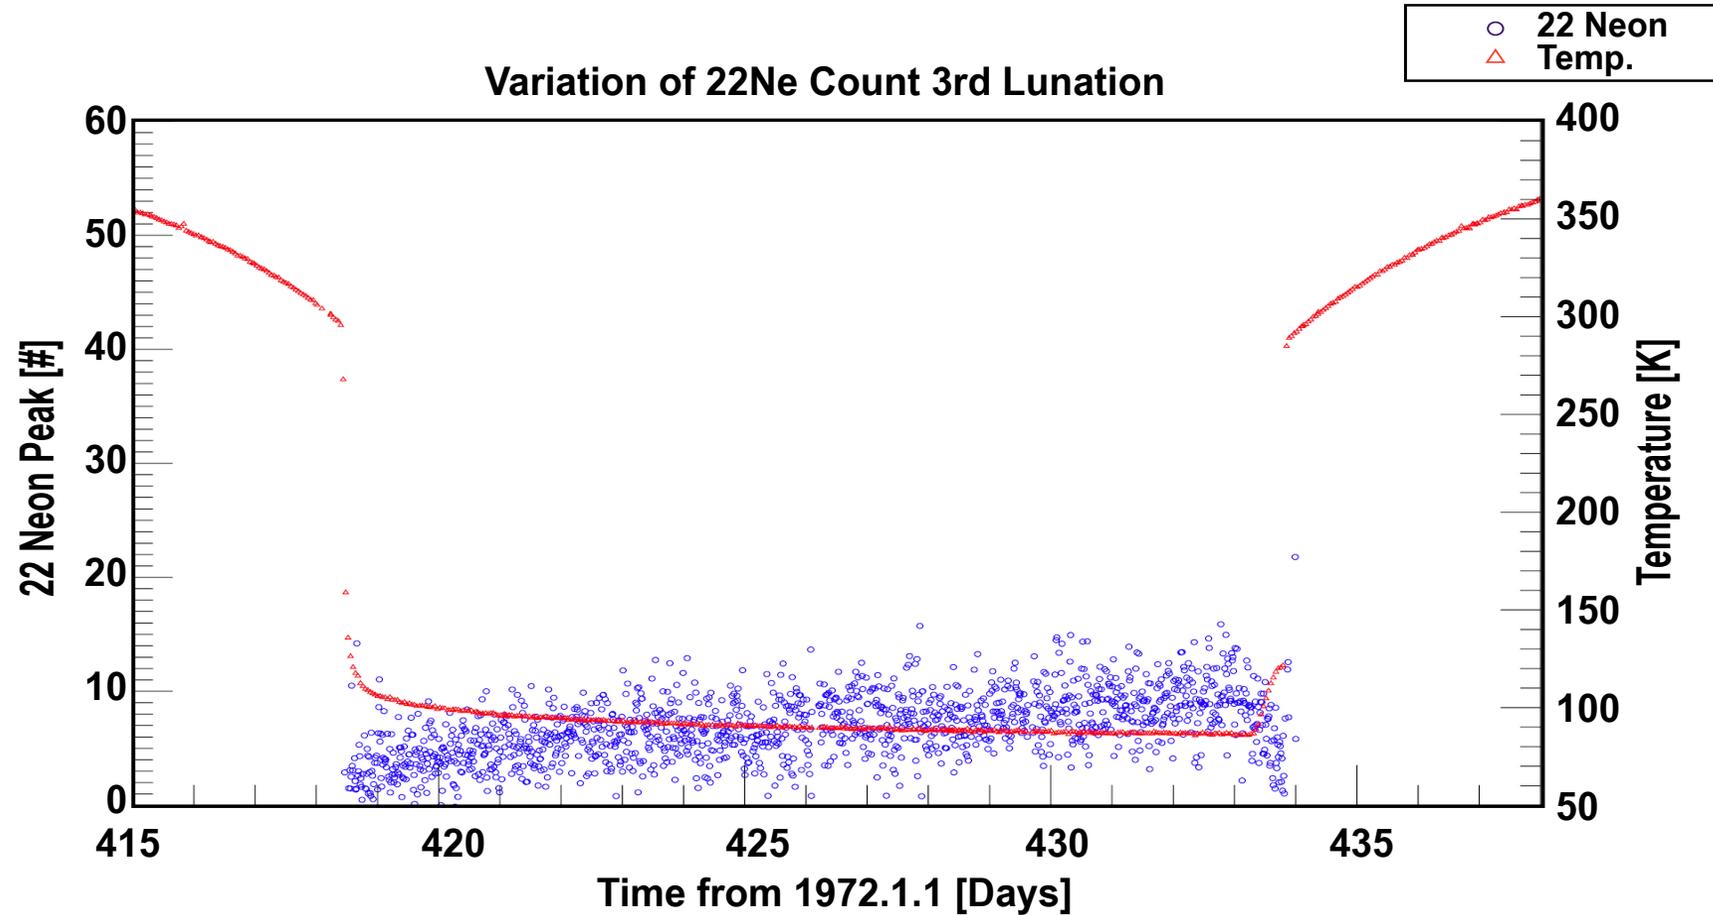

# Description of the Project

- Apollo 17 carried a mass spectrometer, called the Lunar Atmospheric Composition Experiment (LACE),
- part of the Apollo Lunar Surface Experiments Package (ALSEP)
- deployed in the Taurus-Littrow Valley
- turned on December 27, 1971
- We reanalyzed these data to determine the Ne density and its variation

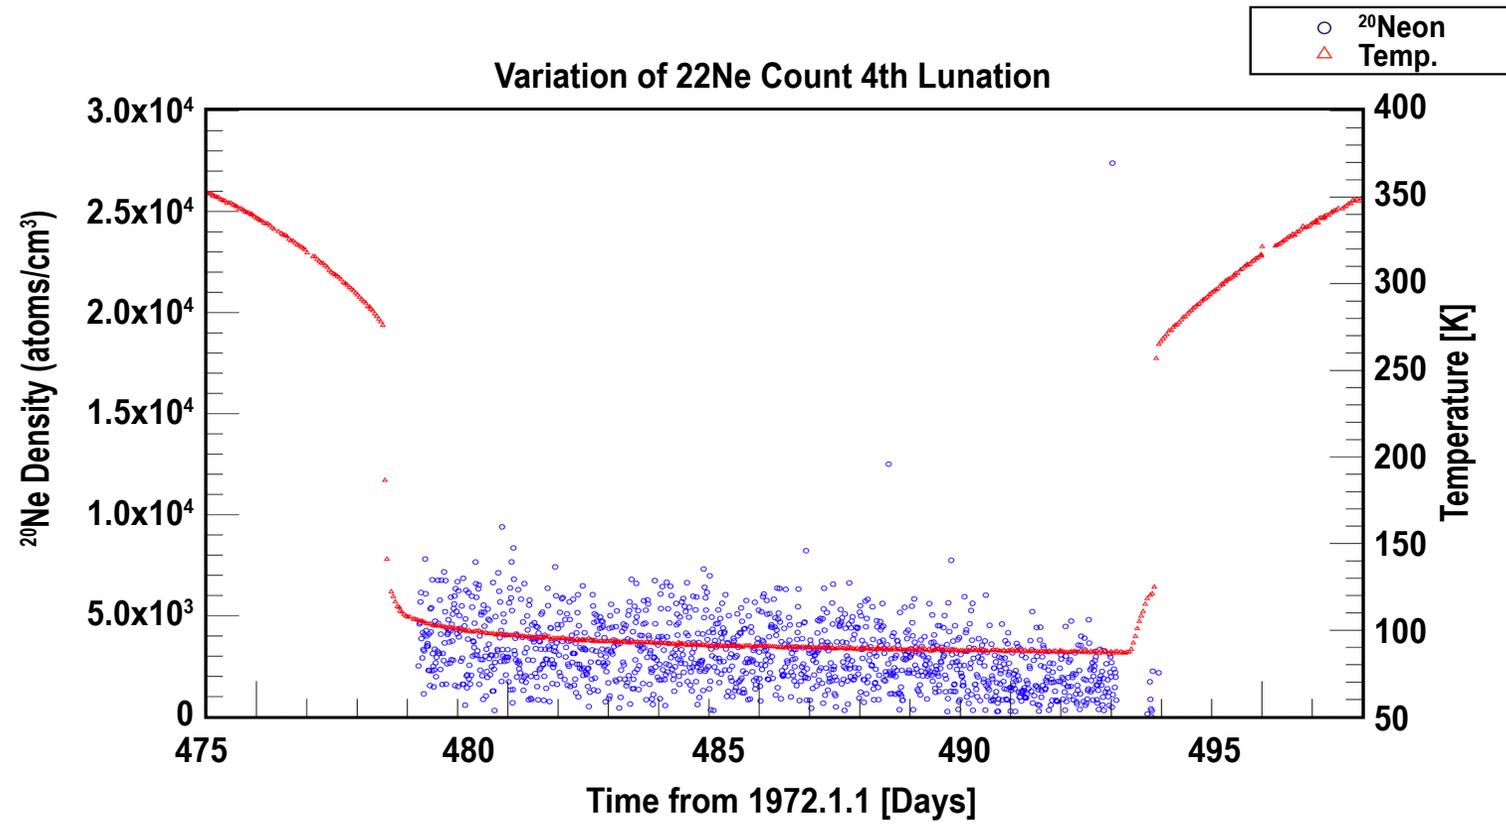

# *Highlights*

- LACE data from Apollo 17 have been reanalyzed
- The  $^{20}\text{Ne}$  nightside surface number densities are  $3 (\pm 1.5) \times 10^3 \text{ cm}^{-3}$
- Our derived Ne abundance cannot be modeled assuming dynamic equilibrium with the solar wind and a photoionization lifetime of 100 days

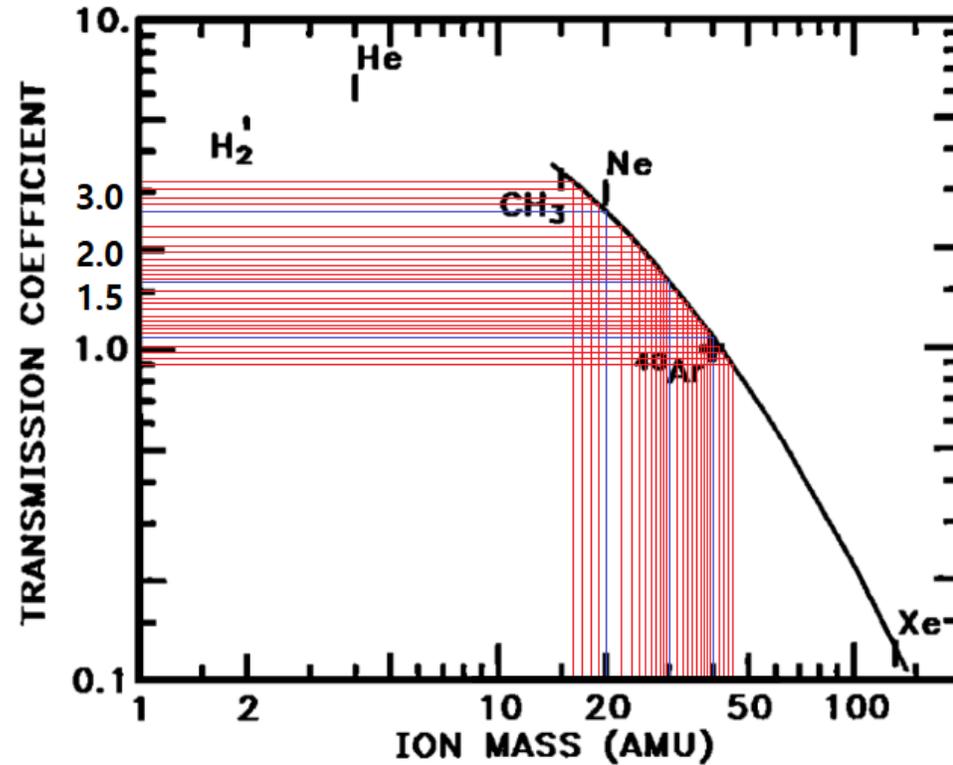

# VARIATION OF Ne SEEN ON 3<sup>RD</sup> LUNATION

# LACE Data for Neon: 4<sup>th</sup> Lunation

# CALIBRATION OF THE DATA

Calibration was performed on an identical Spectrograph that flew on a Venus mission

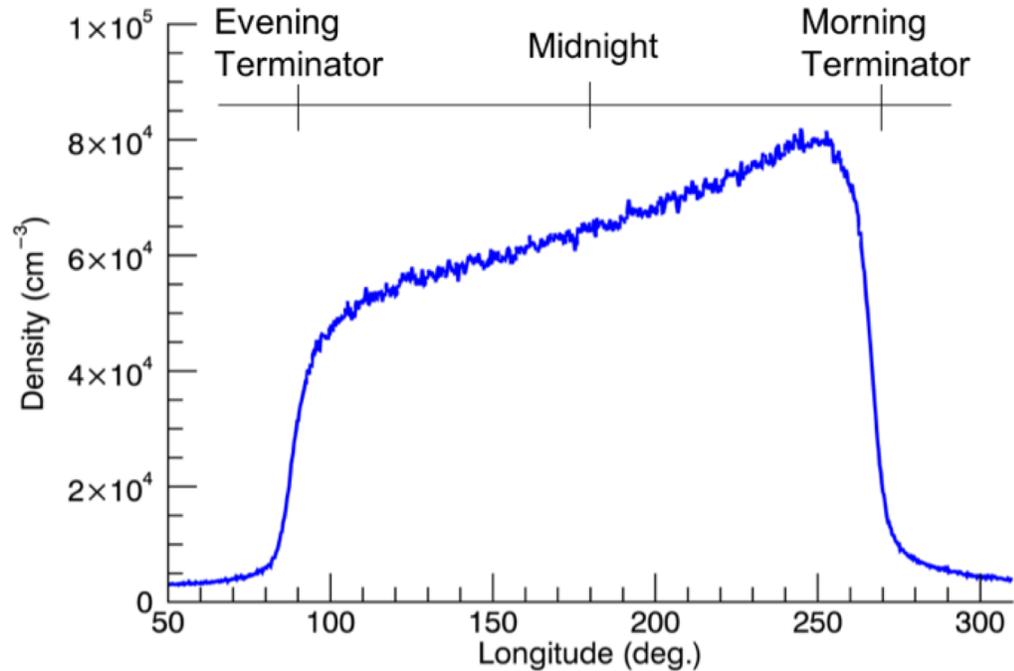

# WE USED M/Q=22 TO INFER $^{20}\text{Ne}$

- M/Q=20 contains  $^{20}\text{Ne}$ , HF, and  $\text{Ar}^{++}$
- M/Q=22 is assumed to be uncontaminated
- $^{22}\text{Ne}$  is 9.25% of all Neon

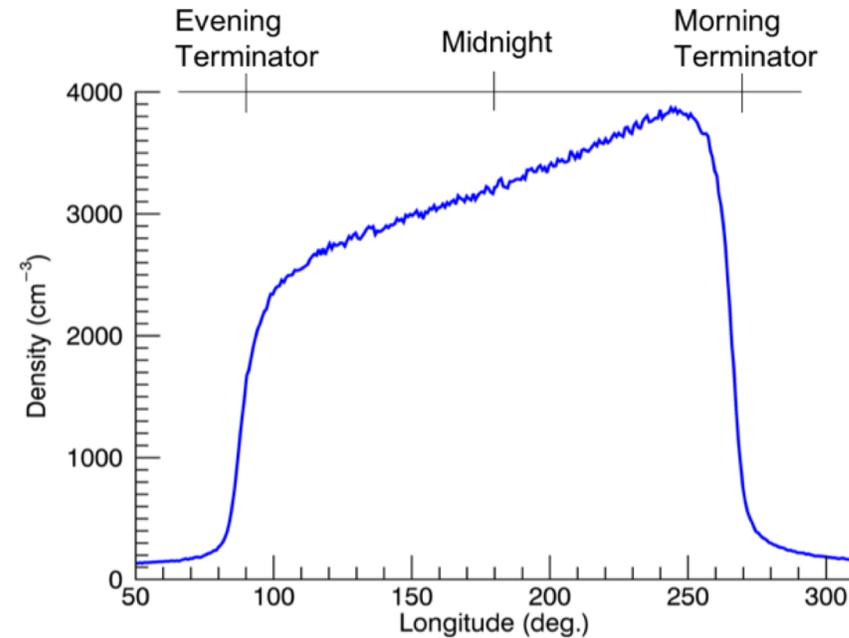

**Table.  $^{20}\text{Ne}$  densities estimated for lunations 2 - 5**

| Lunation        | Dates                  | $^{20}\text{Ne}$ Density                     |
|-----------------|------------------------|----------------------------------------------|
| 2 <sup>nd</sup> | Jan. 24 - Feb. 8, 1973 | $(1.5 - 3.5) \times 10^3 \text{ atoms/cm}^3$ |
| 3 <sup>rd</sup> | Feb. 22 - Mar. 9, 1973 | $(2.0 - 4.5) \times 10^3 \text{ atoms/cm}^3$ |
| 4 <sup>th</sup> | Mar. 24 - Apr. 8, 1973 | $(2.0 - 4.0) \times 10^3 \text{ atoms/cm}^3$ |
| 5 <sup>th</sup> | Apr. 23 - May 7, 1973  | $(2.0 - 4.0) \times 10^3 \text{ atoms/cm}^3$ |

# SIMULATIONS

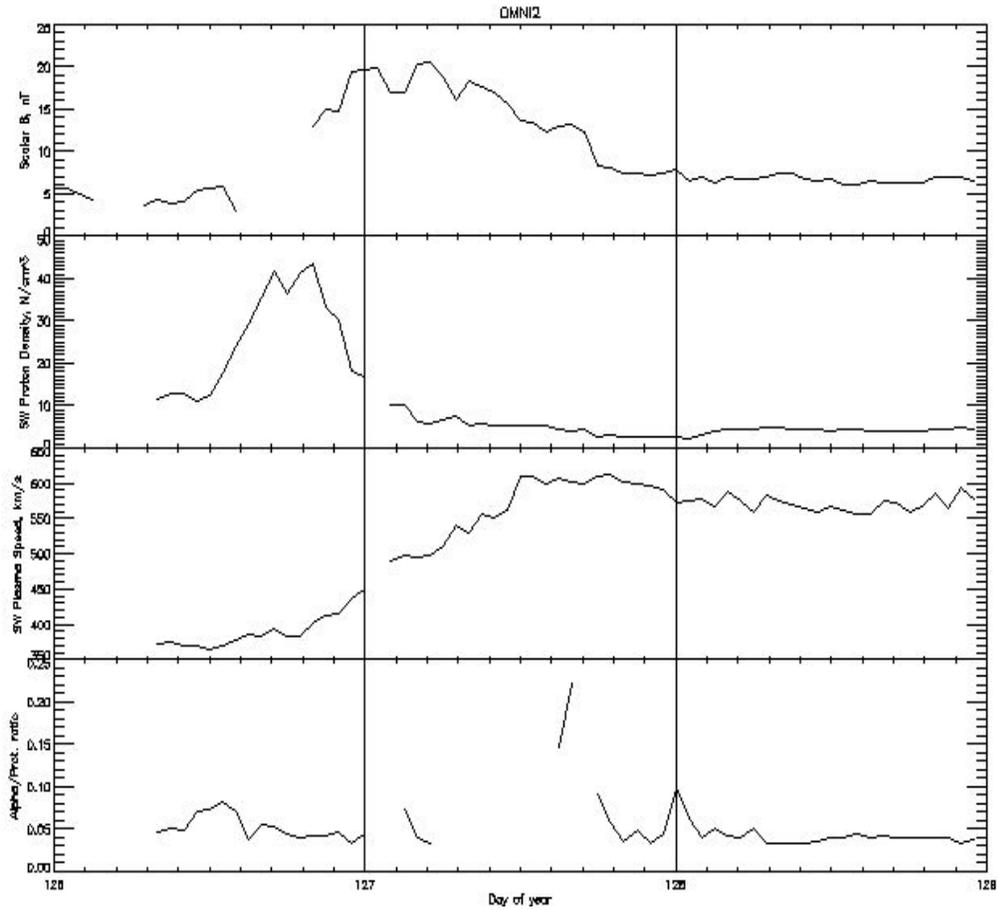

LIFETIME = 100 DAYS

LIFETIME = 4.5 DAYS

Simulations (1, 2) of neon density at TL using nominal SW flux  $N_{SW}v_{SW}(\text{Ne}) = 1.65 \times 10^4 \text{ cm}^{-2}\text{s}^{-1}$  and the photoionization lifetime of 100 days (a) and 4.5 days (b).

# SOLAR WIND DATA DOY 126 - 128

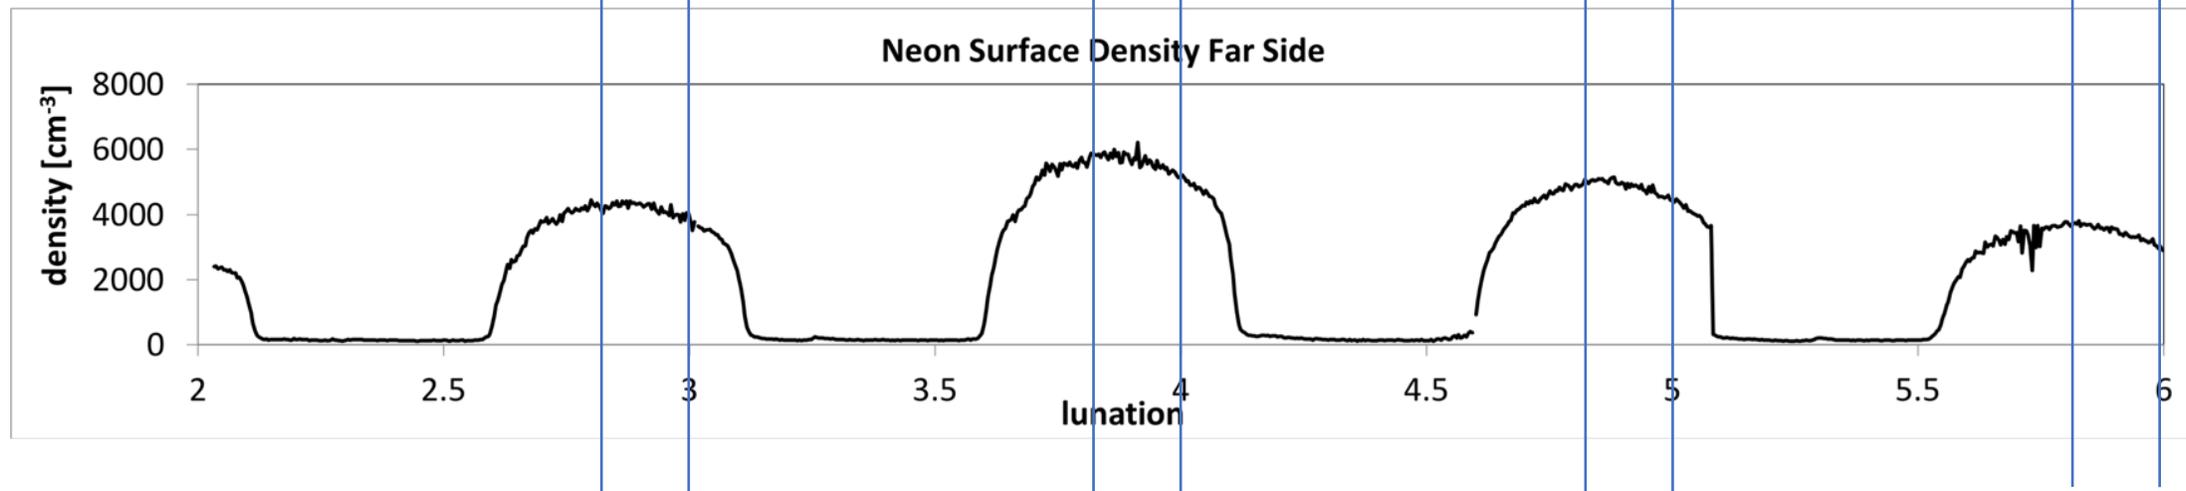

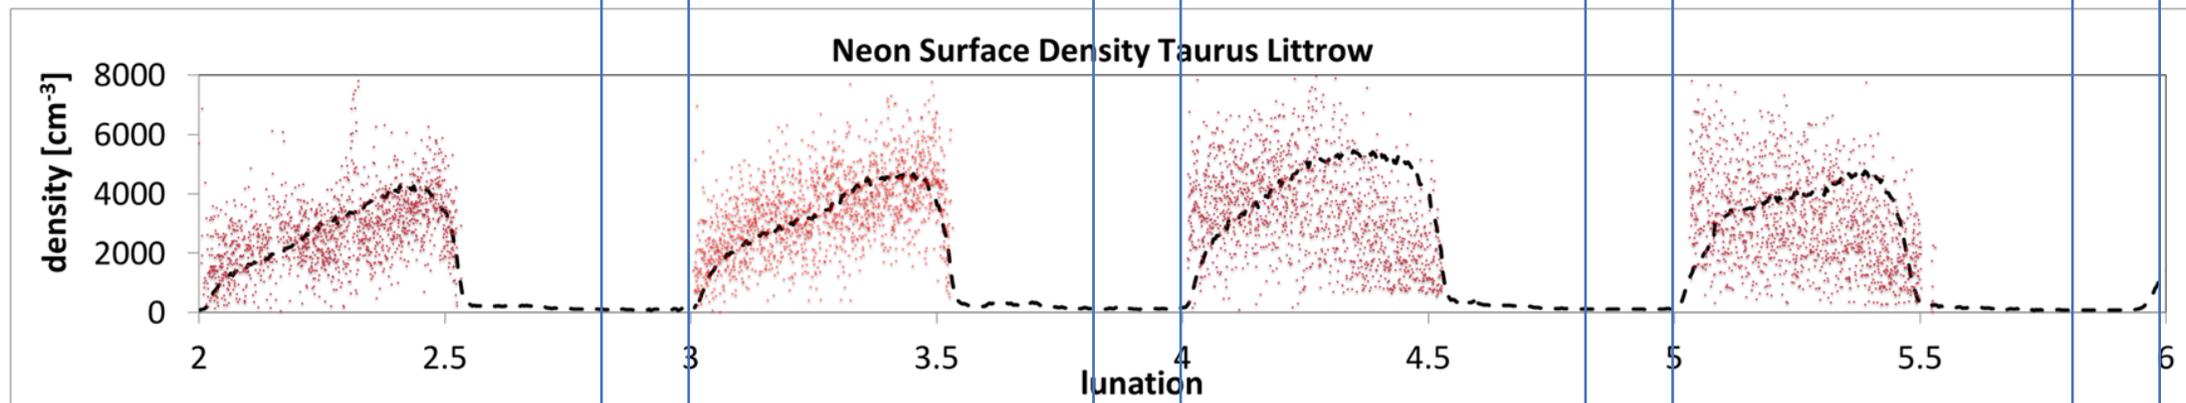

Magnetic Field

Proton density

Solar Wind Speed

He<sup>++</sup>/H<sup>+</sup> Ratio

Magnetotail  
crossings

# COMPARISON WITH OTHER OBSERVATIONS

- COOK ET AL., 2013       $4.4 \times 10^3 \text{ CM}^{-3}$       LRO/LAMP
- BENNA ET AL, 2015       $2.0 \times 10^4 \text{ CM}^{-3}$       LADEE

# Comparison with CHANCE

(Chandra's Altitudinal Composition Explorer)

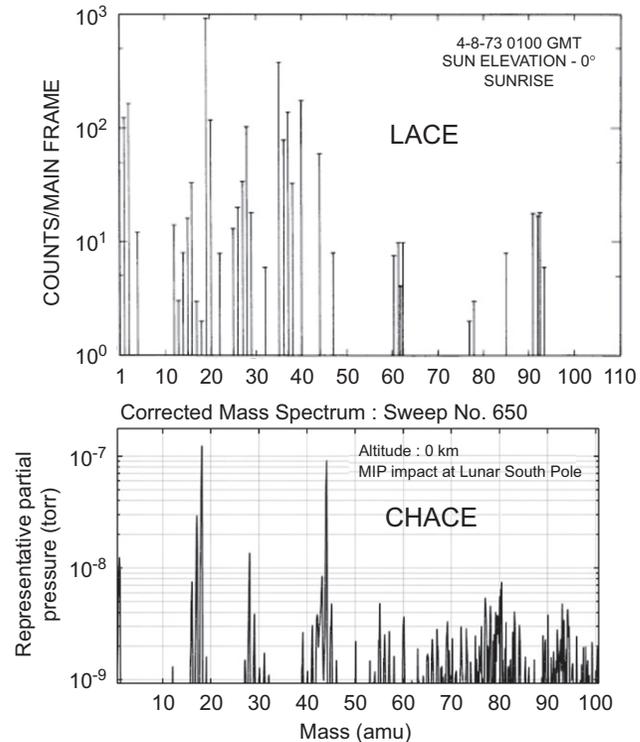

Fig. 10. Comparison between the mass spectra obtained by LACE in Apollo 17 mission (top) (Hoffman et al., 1973) and CHACE in Chandrayaan I mission (bottom). The former corresponds to over the surface, at equatorial region and sunrise time while the latter corresponds to close to the surface over south pole.

LACE, data obtained near the equator shows **significant Neon**.

CHANCE, data obtained at the South Pole to 50 S, shows **no neon**.

The dominant species are H<sub>2</sub>O and CO<sub>2</sub>  
POSSIBLY ARTIFACTS?

They report a “clutter” of species near 80 AMU not seen by LACE, or reported as noise.

# TWO POSSIBLE CONCLUSIONS

- THE DATA ARE CORRECT AND THE LIFETIME IN THE EXOSPHERE IS LESS THAN THE PHOTOIONIZATION LIFETIME
- THE DATA ARE INCORRECT AND THE LIFETIME COULD BE THE PHOTOIONIZATION LIFETIME

# *REMAINING QUESTIONS*

- WHY DOES THE NIGHTSIDE NEON DECREASE SOMETIMES?
- WHAT IS THE TRUE LIFETIME OF NEON IN THE EXOSPHERE?
- WHAT DOES THE NEON EXOSPHERE LOOK LIKE ON THE DAYSIDE?
